CS61C Discussion 4 – RISC-V Addressing, Inst. Formats, and CALL

1 RISC-V Addressing

1.1 Overview

- We have several **addressing modes** to access memory (immediate not listed):
  (a) **Base displacement addressing:** Adds an immediate to a register value to create a memory address (used for lw, lb, sw, sb)
  (b) **PC-relative addressing:** Uses the PC and adds the immediate value of the instruction (multiplied by 2) to create an address (used by branch and jump instructions)
  (c) **Register Addressing:** Uses the value in a register as a memory address (jr)

1.2 Exercises

1. What is range of 32-bit instructions that can be reached from the current PC using a branch instruction?

2. What is the range of 32-bit instructions that can be reached from the current PC using a jump instruction?

3. Given the following RISC-V code (and instruction addresses), fill in the blank fields for the following instructions (you'll need your RISC-V green card!).

```
0x002cff00: loop: add t1, t2, t0          |________|________|________|________|________|__0x33__|
0x002cff04:       jal ra, foo             |____________________________|_________________|__0x6F__|
0x002cff08:       bne t1, zero, loop      |________|________|________|________|________|__0x63__|
...
0x002cff2c: foo:  jr ra                 ra=____________________
```

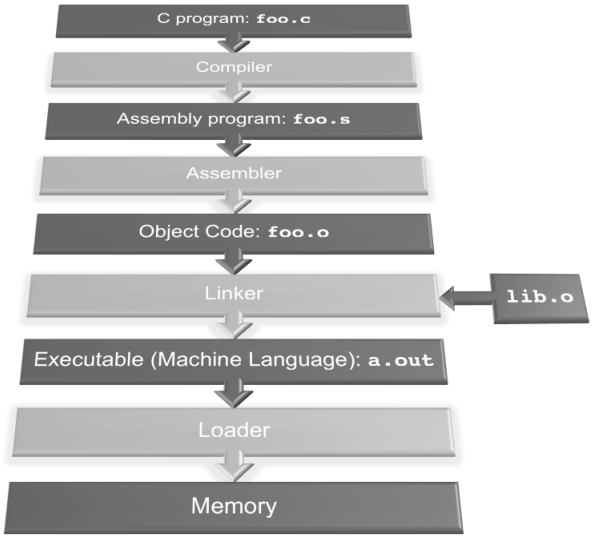
2 Powerful RISC-V Functions

1. Write a function `double` in RISC-V that, when given an integer x, returns $2x$.

2. Write a function `power` in RISC-V that takes in two numbers x and n, and returns x^n. You may assume that $n \geq 0$ and that multiplication will always result in a 32-bit number.

3 Compile, Assemble, Link, Load, and Go!

3.1 Overview



3.2 Exercises

a. What is the Stored Program concept and what does it enable us to do?

b. How many passes through the code does the Assembler have to make? Why?

c. What are the different parts of the object files output by the Assembler?

d. Which step in CALL resolves relative addressing? Absolute addressing?

e. What does RISC stand for? How is this related to pseudoinstructions?

4 Writing RISC-V Functions

Write a function `sumSquare` in RISC-V that, when given an integer `n`, returns the summation below. If `n` is not positive, then the function returns 0.

$$n^2 + (n-1)^2 + (n-2)^2 + \ldots + 1^2$$

For this problem, you are given a RISC-V function called `square` that takes in an integer and returns its square. Implement `sumSquare` using `square` as a subroutine.

RISC-V Reference Data Card ("Green Card") 1. Pull along perforation to separate card 2. Fold bottom side (columns 3 and 4) together

① RISC-V Reference Data

RV64I BASE INTEGER INSTRUCTIONS, in alphabetical order

xori	I	XOR Immediate	R[rd] = R[rs1] ^ imm	

Notes: 1) The Word version only operates on the rightmost 32 bits of a 64-bit registers
2) Operation assumes unsigned integers (instead of 2's complement)
3) The least significant bit of the branch address in jalr is set to 0
4) (signed) Load instructions extend the sign bit of data to fill the 64-bit register
5) Replicates the sign bit to fill in the leftmost bits of the result during right shift
6) Multiply with one operand signed and one unsigned
7) The Single version does a single-precision operation using the rightmost 32 bits of a 64-bit F register
8) Classify writes a 10-bit mask to show which properties are true (e.g., –inf, -0,+0, +inf, denorm, ...)
9) Atomic memory operation; nothing else can interpose itself between the read and the write of the memory location
The immediate field is sign-extended in RISC-V
