Operating Systems and Systems Programming
Lecture 5

Introduction to Networking, Concurrency (Processes and Threads)

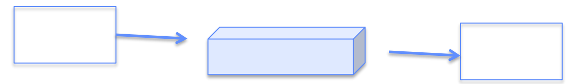
January 31st, 2018

Profs. Anthony D. Joseph and Jonathan Ragan-Kelley
http://cs162.eecs.Berkeley.edu

Recall: Communication between processes

- Can we view files as communication channels?

```
write(wfd, wbuf, wlen);
```

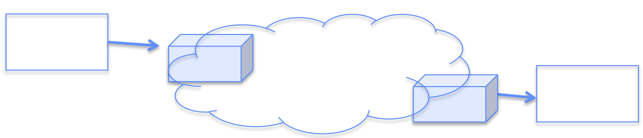


```
n = read(rfd,rbuf,rmax);
```

- Producer and Consumer of a file may be distinct processes
  - May be separated in time (or not)
- However, what if data written once and consumed once?
  - Don't we want something more like a queue?
  - Can still look like File I/O!

Communication Across the world looks like file IO

```
write(wfd, wbuf, wlen);
```



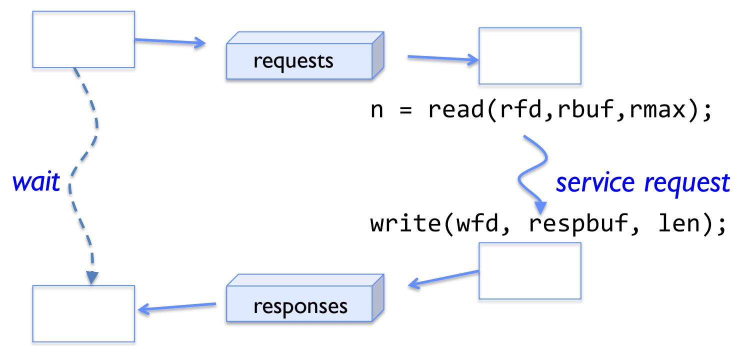
```
n = read(rfd,rbuf,rmax);
```

- Connected queues over the Internet
  - But what's the analog of open?
  - What is the namespace?
  - How are they connected in time?

Request Response Protocol

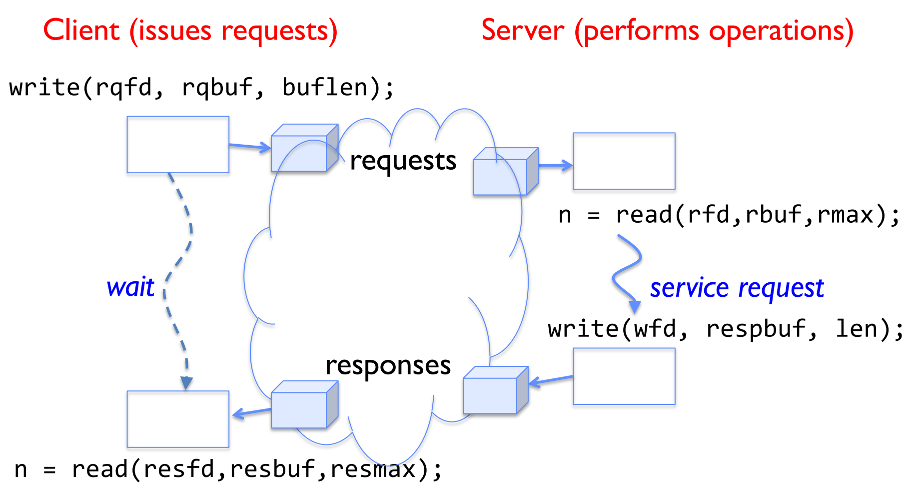
Client (issues requests) Server (performs operations)

```
write(rqfd, rqbuf, buflen);
```

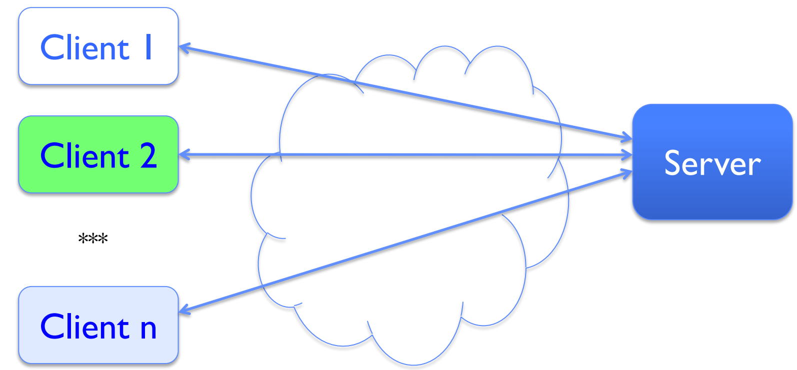


```
n = read(resfd,resbuf,resmax);
```

Request Response Protocol



Client-Server Models

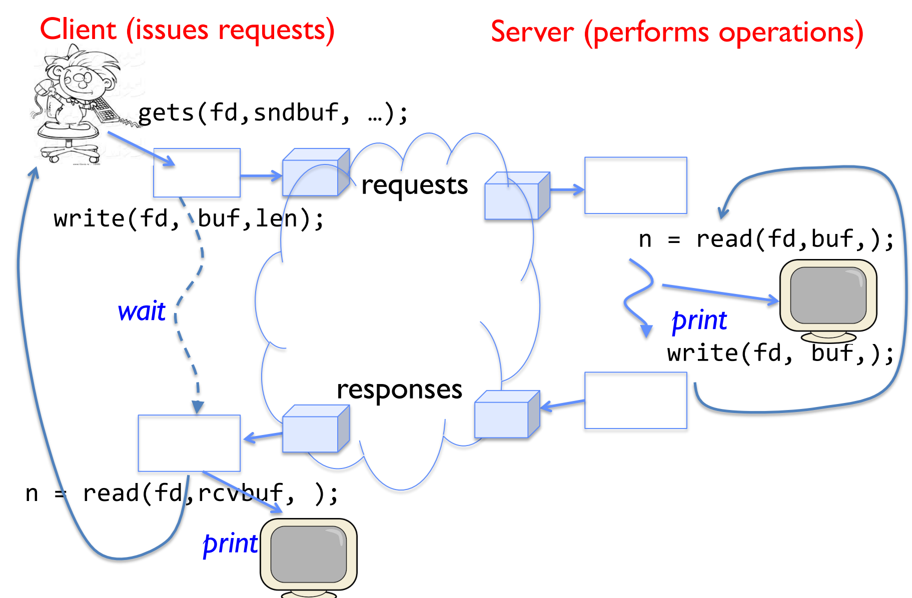


- File servers, web, FTP, Databases, …
- Many clients accessing a common server

Sockets

- Socket: an abstraction of a network I/O queue
  - Mechanism for inter-process communication
  - Embodies one side of a communication channel
    - » Same interface regardless of location of other end
    - » Local machine ("UNIX socket") or remote machine ("network socket")
  - First introduced in 4.2 BSD UNIX: big innovation at time
    - » Now most operating systems provide some notion of socket
- Data transfer like files
  - Read / Write against a descriptor
- Over ANY kind of network
  - Local to a machine
  - Over the internet (TCP/IP, UDP/IP)
  - OSI, Appletalk, SNA, IPX, SIP, NS, …

Silly Echo Server – running example



Echo client-server example

```
void client(int sockfd) {
  int n;
  char sndbuf[MAXIN]; char rcvbuf[MAXOUT];
  getreq(sndbuf, MAXIN);        /* prompt */
  while (strlen(sndbuf) > 0) {
    write(sockfd, sndbuf, strlen(sndbuf)); /* send */
    memset(rcvbuf,0,MAXOUT);              /* clear */
    n=read(sockfd, rcvbuf, MAXOUT-1);     /* receive */
    write(STDOUT_FILENO, rcvbuf, n);        /* echo */
    getreq(sndbuf, MAXIN);                /* prompt */
  }
}
```

```
void server(int consockfd) {
  char reqbuf[MAXREQ];
  int n;
  while (1) {
    memset(reqbuf,0, MAXREQ);
    n = read(consockfd,reqbuf,MAXREQ-1); /* Recv */
    if (n <= 0) return;
    n = write(STDOUT_FILENO, reqbuf, strlen(reqbuf));
    n = write(consockfd, reqbuf, strlen(reqbuf)); /* echo*/
  }
}
```

Prompt for input

```
char *getreq(char *inbuf, int len) {
  /* Get request char stream */
  printf("REQ: ");              /* prompt */
  memset(inbuf,0,len);          /* clear for good measure */
  return fgets(inbuf,len,stdin); /* read up to a EOL */
}
```

Socket creation and connection

- File systems provide a collection of permanent objects in structured name space
  - Processes open, read/write/close them
  - Files exist independent of the processes
- Sockets provide a means for processes to communicate (transfer data) to other processes.
- Creation and connection is more complex
- Form 2-way pipes between processes
  - Possibly worlds away

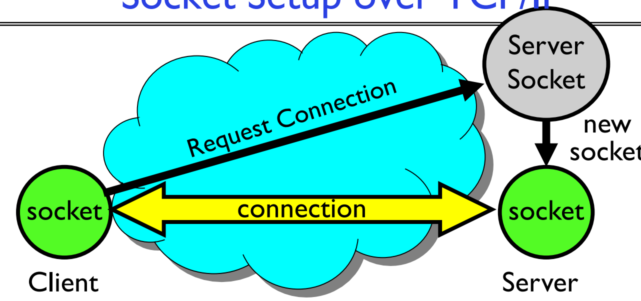
Namespaces for communication over IP

- Hostname
  - www.eecs.berkeley.edu
- IP address
  - 128.32.244.172 (IPv4 32-bit)
  - fe80::4ad7:5ff:fecf:2607 (IPv6 128-bit)
- Port Number
  - 0-1023 are "well known" or "system" ports
    - » Superuser privileges to bind to one
  - 1024 – 49151 are "registered" ports (registry)
    - » Assigned by IANA for specific services
  - 49152–65535 ($2^{15}+2^{14}$ to $2^{16}-1$) are "dynamic" or "private"
    - » Automatically allocated as "ephemeral Ports"

Using Sockets for Client-Server (C/C++)

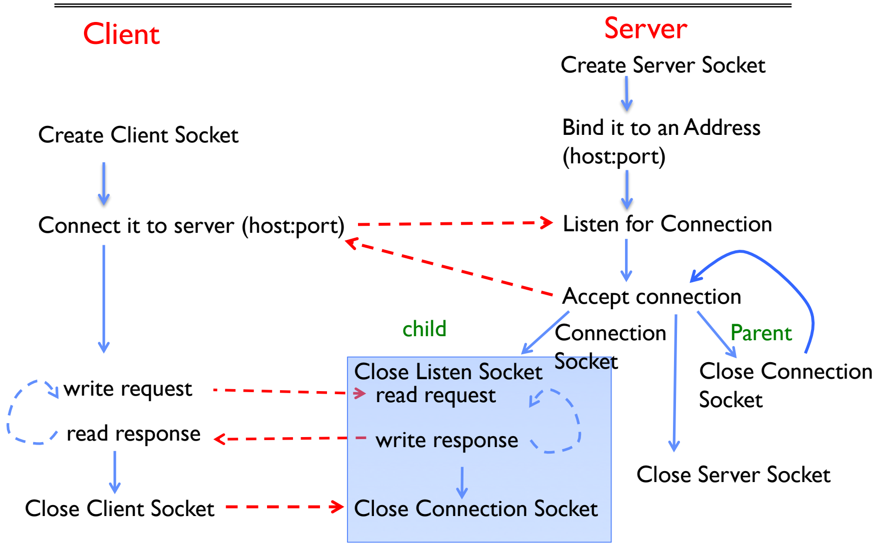
- On server: set up "server-socket"
  - Create socket; bind to protocol (TCP), local address, port
  - Call `listen()`: tells server socket to accept incoming requests
  - Perform multiple `accept()` calls on socket to accept incoming connection request
  - Each successful `accept()` returns a new socket for a new connection; can pass this off to handler thread
- On client:
  - Create socket; bind to protocol (TCP), remote address, port
  - Perform `connect()` on socket to make connection
  - If `connect()` successful, have socket connected to server

Socket Setup over TCP/IP



- Server Socket: Listens for new connections
  - Produces new sockets for each unique connection
- Things to remember:
  - Connection involves 5 values:
    [Client Addr, Client Port, Server Addr, Server Port, Protocol]
  - Often, Client Port "randomly" assigned by OS during client socket setup
  - Server Port often "well known" (0-1023)
    - » 80 (web), 443 (secure web), 25 (sendmail), etc

Example: Server Protection and Parallelism



Server Protocol (v3)

```
listen(lstnsockfd, MAXQUEUE);
while (1) {
    consockfd = accept(lstnsockfd, (struct sockaddr *) &cli_addr,
                                                       &clilen);
    cpid = fork();              /* new process for connection */
    if (cpid > 0) {             /* parent process */
      close(consockfd);
      //tcpid = wait(&cstatus);
    } else if (cpid == 0) {      /* child process */
      close(lstnsockfd);        /* let go of listen socket */

      server(consockfd);

      close(consockfd);
      exit(EXIT_SUCCESS);         /* exit child normally */
    }
  }
close(lstnsockfd);
```

Server Address - Itself

```
struct sockaddr_in {
  short sin_family;  // address family, e.g., AF_INET
  unsigned short sin_port; // port # (in network byte ordering)
  struct in_addr sin_addr; // host address
  char sin_zero[8]; // for padding to cast it to sockaddr
} serv_addr;

memset((char *) &serv_addr,0, sizeof(serv_addr));
serv_addr.sin_family      = AF_INET;  // Internet address family
serv_addr.sin_addr.s_addr = INADDR_ANY; // get host address
serv_addr.sin_port        = htons(portno);
```

- Simple form
- Internet Protocol
- accepting any connections on the specified port
- In "network byte ordering" (which is *big endian*)

Client: Getting the Server Address

```
struct hostent *buildServerAddr(struct sockaddr_in *serv_addr,
                                char *hostname, int portno) {
  struct hostent *server;

  /* Get host entry associated with a hostname or IP address */
  server = gethostbyname(hostname);
  if (server == NULL) {
    fprintf(stderr,"ERROR, no such host\n");
    exit(1);
  }

  /* Construct an address for remote server */
  memset((char *) serv_addr, 0, sizeof(struct sockaddr_in));
  serv_addr->sin_family = AF_INET;
  bcopy((char *)server->h_addr,
        (char *)&(serv_addr->sin_addr.s_addr), server->h_length);
  serv_addr->sin_port = htons(portno);

  return server;
}
```

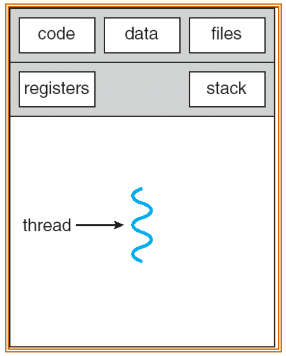
Administrivia

- Group Creation deadline is Friday 2/2 at 11:59PM
- TA preferences due Monday 2/5 at 11:59PM
  – We will try to accommodate your needs, but have to balance both over-popular and under-popular sections
- Attend section and get to know your TAs!

BREAK

Recall: Traditional UNIX Process

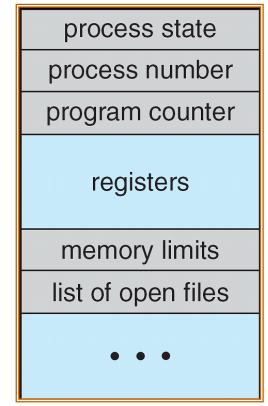
- Process: OS abstraction of what is needed to run a single program
  – Often called a "Heavyweight Process"
  – No concurrency in a "Heavyweight Process"



- Two parts:
  – Sequential program execution stream [ACTIVE PART]
    » Code executed as a sequential stream of execution (i.e., thread)
    » Includes State of CPU registers
  – Protected resources [PASSIVE PART]:
    » Main memory state (contents of Address Space)
    » I/O state (i.e. file descriptors)

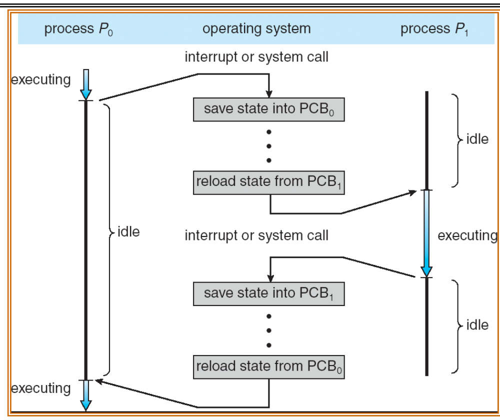
How do we Multiplex Processes?

- The current state of process held in a process control block (PCB):
  – This is a "snapshot" of the execution and protection environment
  – Only one PCB active at a time
- Give out CPU time to different processes (Scheduling):
  – Only one process "running" at a time
  – Give more time to important processes
- Give pieces of resources to different processes (Protection):
  – Controlled access to non-CPU resources
  – Example mechanisms:
    » Memory Translation: Give each process their own address space
    » Kernel/User duality: Arbitrary multiplexing of I/O through system calls



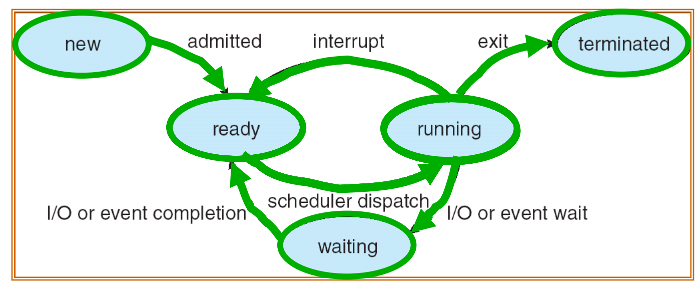
Process Control Block

CPU Switch From Process A to Process B



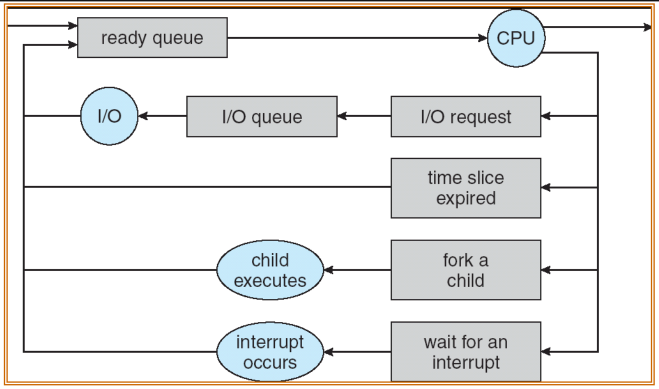
- This is also called a "context switch"
- Code executed in kernel above is ***overhead***
  – Overhead sets minimum practical switching time
  – Less overhead with SMT/hyperthreading, but… contention for resources instead

Lifecycle of a Process



- As a process executes, it changes state:
  – new: The process is being created
  – ready: The process is waiting to run
  – running: Instructions are being executed
  – waiting: Process waiting for some event to occur
  – terminated: The process has finished execution

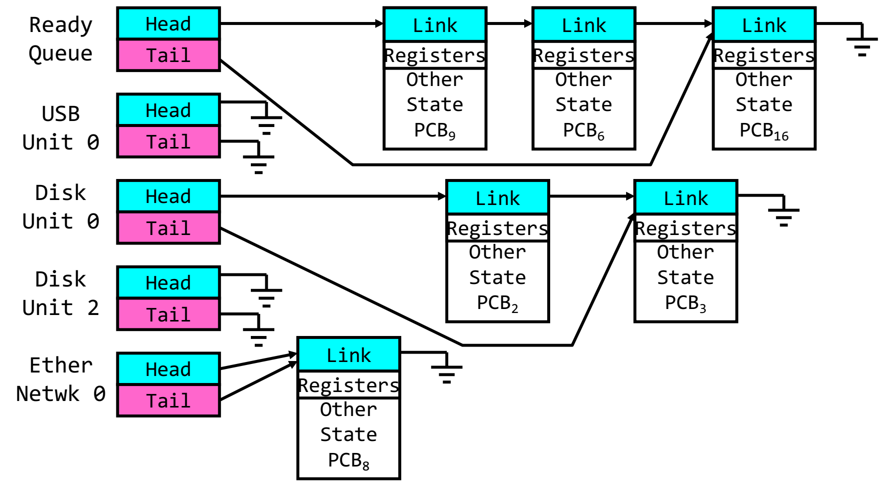
Process Scheduling



- PCBs move from queue to queue as they change state
  - Decisions about which order to remove from queues are Scheduling decisions
  - Many algorithms possible (few weeks from now)

Ready Queue And Various I/O Device Queues

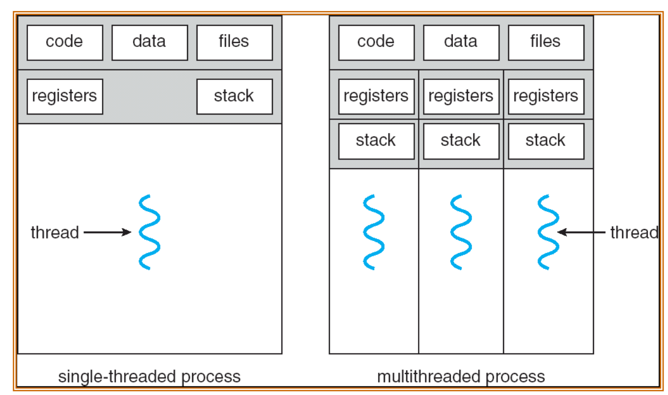
- Process not running ⇒ PCB is in some scheduler queue
  - Separate queue for each device/signal/condition
  - Each queue can have a different scheduler policy



Modern Process with Threads

- Thread: *a sequential execution stream within process* (Sometimes called a "Lightweight process")
  - Process still contains a single Address Space
  - No protection between threads
- Multithreading: *a single program made up of a number of different concurrent activities*
  - Sometimes called multitasking, as in Ada …
- Why separate the concept of a thread from that of a process?
  - Discuss the "thread" part of a process (concurrency)
  - Separate from the "address space" (protection)
  - Heavyweight Process ≡ Process with one thread

Recall: Single and Multithreaded Processes

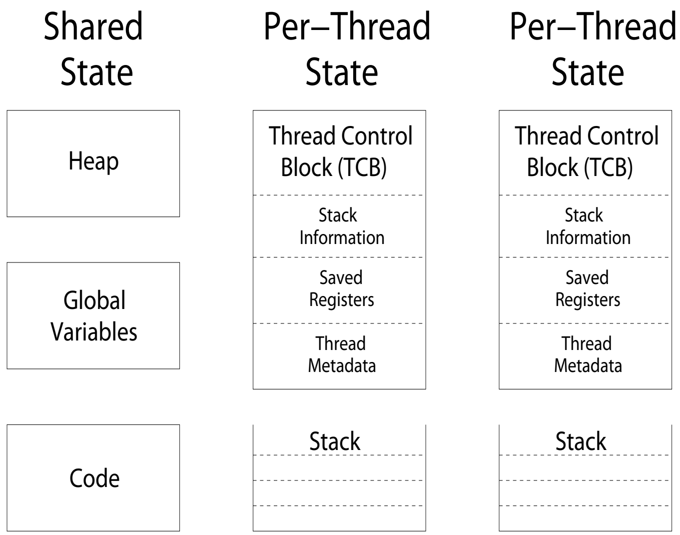


- Threads encapsulate concurrency: "Active" component
- Address spaces encapsulate protection: "Passive" part
  - Keeps buggy program from trashing the system
- Why have multiple threads per address space?

Thread State

- State shared by all threads in process/address space
  - Content of memory (global variables, heap)
  - I/O state (file descriptors, network connections, etc)
- State "private" to each thread
  - Kept in TCB ≡ Thread Control Block
  - CPU registers (including, program counter)
  - Execution stack – what is this?
- Execution Stack
  - Parameters, temporary variables
  - Return PCs are kept while called procedures are executing

Shared vs. Per-Thread State



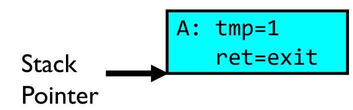
Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```



- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
          A(int tmp) {
A:          if (tmp<2)
A+1:          B();
A+2:        printf(tmp);
          }
          B() {
B:          C();
B+1:      }
          C() {
C:          A(2);
C+1:      }
          A(1);
exit:
```

Stack Pointer → A: tmp=1 ret=exit

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
          A(int tmp) {
A:          if (tmp<2)
A+1:          B();
A+2:        printf(tmp);
          }
          B() {
B:          C();
B+1:      }
          C() {
C:          A(2);
C+1:      }
          A(1);
exit:
```

Stack Pointer → A: tmp=1 ret=exit

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
          A(int tmp) {
A:          if (tmp<2)
A+1:          B();
A+2:        printf(tmp);
          }
          B() {
B:          C();
B+1:      }
          C() {
C:          A(2);
C+1:      }
          A(1);
exit:
```

A: tmp=1 ret=exit

Stack Pointer → B: ret=A+2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
          A(int tmp) {
A:          if (tmp<2)
A+1:          B();
A+2:        printf(tmp);
          }
          B() {
B:          C();
B+1:      }
          C() {
C:          A(2);
C+1:      }
          A(1);
exit:
```

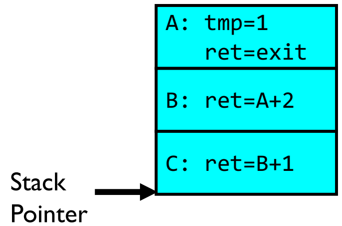
A: tmp=1 ret=exit

Stack Pointer → B: ret=A+2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

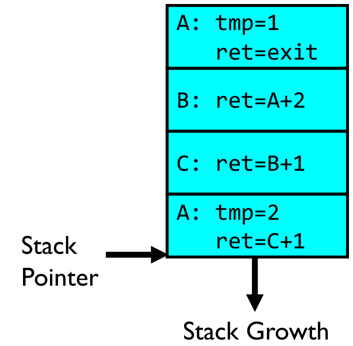
```
       A(int tmp) {
A:       if (tmp<2)
A+1:       B();
A+2:     printf(tmp);
       }
       B() {
B:       C();
B+1:   }
       C() {
C:       A(2);
C+1:   }
       A(1);
exit:
```



- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

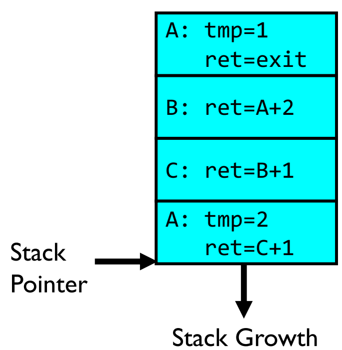
```
       A(int tmp) {
A:       if (tmp<2)
A+1:       B();
A+2:     printf(tmp);
       }
       B() {
B:       C();
B+1:   }
       C() {
C:       A(2);
C+1:   }
       A(1);
exit:
```



- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
       A(int tmp) {
A:       if (tmp<2)
A+1:       B();
A+2:     printf(tmp);
       }
       B() {
B:       C();
B+1:   }
       C() {
C:       A(2);
C+1:   }
       A(1);
exit:
```

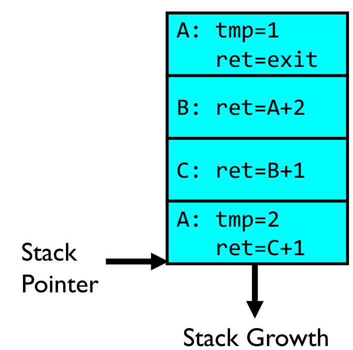


Output: >2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
       A(int tmp) {
A:       if (tmp<2)
A+1:       B();
A+2:     printf(tmp);
       }
       B() {
B:       C();
B+1:   }
       C() {
C:       A(2);
C+1:   }
       A(1);
exit:
```

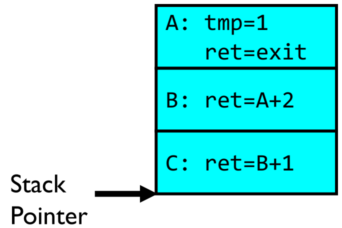


Output: >2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```

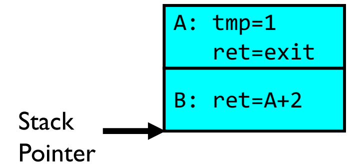


Output: >2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```



Output: >2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```

Output: >2 1

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
      A(int tmp) {
A:      if (tmp<2)
A+1:      B();
A+2:    printf(tmp);
      }
      B() {
B:      C();
B+1:  }
      C() {
C:      A(2);
C+1:  }
      A(1);
exit:
```

Output: >2 1

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
A(int tmp) {
  if (tmp<2)
    B();
  printf(tmp);
}
B() {
  C();
}
C() {
  A(2);
}
A(1);
```

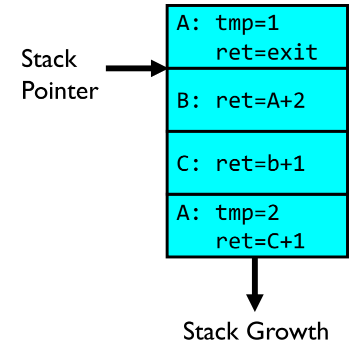
Output: `>2 1`

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Execution Stack Example

```
A(int tmp) {
  if (tmp<2)
    B();
  printf(tmp);
}
B() {
  C();
}
C() {
  A(2);
}
A(1);
```



- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Motivational Example for Threads

- Imagine the following C program:

```
main() {
   ComputePI("pi.txt");
   PrintClassList("classlist.txt");
}
```

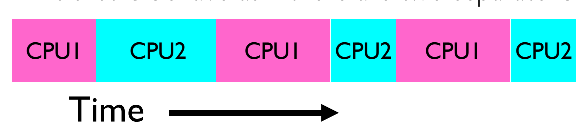
- What is the behavior here?
  - Program would never print out class list
  - Why? `ComputePI` would never finish

Use of Threads

- Version of program with Threads (loose syntax):

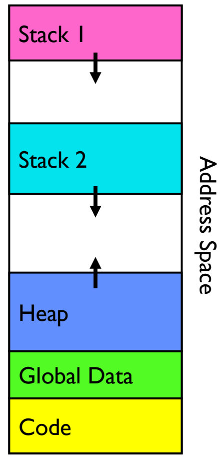
```
main() {
   ThreadFork(ComputePI, "pi.txt"));
   ThreadFork(PrintClassList, "classlist.txt"));
}
```

- What does `ThreadFork()` do?
  - Start independent thread running given procedure
- What is the behavior here?
  - Now, you would actually see the class list
  - This *should* behave as if there are two separate CPUs



Memory Footprint: Two-Threads

- If we stopped this program and examined it with a debugger, we would see
  – Two sets of CPU registers
  – Two sets of Stacks
- Questions:
  – How do we position stacks relative to each other?
  – What maximum size should we choose for the stacks?
  – What happens if threads violate this?
  – How might you catch violations?



Actual Thread Operations

- `thread_fork(func, args)`
  – Create a new thread to run func(args)
  – Pintos: `thread_create`
- `thread_yield()`
  – Relinquish processor voluntarily
  – Pintos: `thread_yield`
- `thread_join(thread)`
  – In parent, wait for forked thread to exit, then return
  – Pintos: `thread_join`
- `thread_exit`
  – Quit thread and clean up, wake up joiner if any
  – Pintos: `thread_exit`
- `pThreads`: POSIX standard for thread programming [POSIX.1c, Threads extensions (IEEE Std 1003.1c-1995)]

Dispatch Loop

- Conceptually, the dispatching loop of the operating system looks as follows:

```
Loop {
   RunThread();
   ChooseNextThread();
   SaveStateOfCPU(curTCB);
   LoadStateOfCPU(newTCB);
}
```

- This is an *infinite* loop
  – One could argue that this is all that the OS does
- Should we ever exit this loop???
  – When would that be?

Running a thread

Consider first portion: `RunThread()`

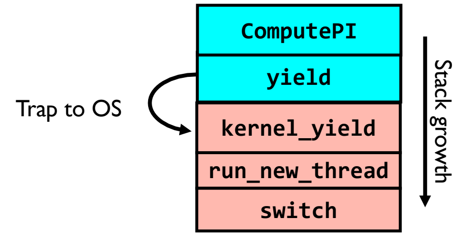
- How do I run a thread?
  – Load its state (registers, PC, stack pointer) into CPU
  – Load environment (virtual memory space, etc)
  – Jump to the PC
- How does the dispatcher get control back?
  – Internal events: thread returns control voluntarily
  – External events: thread gets *preempted*

Internal Events

- Blocking on I/O
  – The act of requesting I/O implicitly yields the CPU
- Waiting on a "signal" from other thread
  – Thread asks to wait and thus yields the CPU
- Thread executes a `yield()`
  – Thread volunteers to give up CPU

```
computePI() {
   while(TRUE) {
      ComputeNextDigit();
      yield();
   }
}
```

Stack for Yielding Thread



- How do we run a new thread?

```
run_new_thread() {
   newThread = PickNewThread();
   switch(curThread, newThread);
   ThreadHouseKeeping(); /* Do any cleanup */
}
```

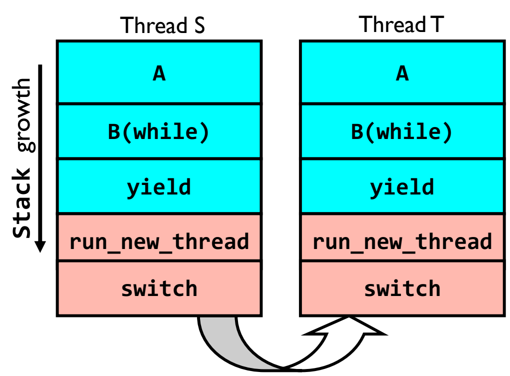
- How does dispatcher switch to a new thread?
  – Save anything next thread may trash: PC, regs, stack pointer
  – Maintain isolation for each thread

What Do the Stacks Look Like?

- Consider the following code blocks:

```
proc A() {
   B();

}
proc B() {
   while(TRUE) {
      yield();
   }
}
```



- Suppose we have 2 threads:
  – Threads S and T

Saving/Restoring state (often called "Context Switch)

```
Switch(tCur,tNew) {
   /* Unload old thread */
   TCB[tCur].regs.r7 = CPU.r7;
         …
   TCB[tCur].regs.r0 = CPU.r0;
   TCB[tCur].regs.sp = CPU.sp;
   TCB[tCur].regs.retpc = CPU.retpc; /*return addr*/

   /* Load and execute new thread */
   CPU.r7 = TCB[tNew].regs.r7;
         …
   CPU.r0 = TCB[tNew].regs.r0;
   CPU.sp = TCB[tNew].regs.sp;
   CPU.retpc = TCB[tNew].regs.retpc;
   return; /* Return to CPU.retpc */
}
```

Switch Details (continued)

- What if you make a mistake in implementing switch?
  - Suppose you forget to save/restore register 32
  - Get intermittent failures depending on when context switch occurred and whether new thread uses register 32
  - System will give wrong result without warning
- Can you devise an exhaustive test to test switch code?
  - No! Too many combinations and inter-leavings
- Cautionary tale:
  - For speed, Topaz kernel saved one instruction in switch()
  - Carefully documented! Only works as long as kernel size < 1MB
  - What happened?
    - » Time passed, People forgot
    - » Later, they added features to kernel (no one removes features!)
    - » Very weird behavior started happening
  - Moral of story: Design for simplicity

Summary

- Socket: an abstraction of a network I/O queue (IPC mechanism)
- Processes have two parts
  - One or more Threads (Concurrency)
  - Address Spaces (Protection)
- Concurrency accomplished by multiplexing CPU Time:
  - Unloading current thread (PC, registers)
  - Loading new thread (PC, registers)
  - Such context switching may be voluntary (`yield()`, I/O operations) or involuntary (timer, other interrupts)
